

Khitan: Understanding the language behind the scripts

Juha A. JANHUNEN

University of Helsinki, FINLAND

In the global context of ancient scripts and their decipherment it is not widely known that some of the last great challenges posed by unknown systems of writing are those connected with the scripts of peripheral mediaeval China. Three non-Chinese ethnic groups—the Khitan, the Jurchen, and the Tangut, corresponding to the “alien” dynasties of Liao 遼 (907-1125), Jin 金 (1115-1234), and Xixia 西夏 (1038-1227), respectively—created scripts and literary languages of their own. After centuries of oblivion, samples of these scripts emerged in the late 19th and early 20th centuries and became objects of intensive study. Even so, we cannot say that any of these scripts has been fully deciphered. The problems vary from script to script, however, and they are also connected with the level of knowledge we have of the underlying languages—Khitan, Jurchen, and

Tangut. It happens that of the three languages, only Jurchen survived till later times, becoming the direct ancestor of Manchu, while both Khitan and Tangut became extinct soon after the fall of the political states that had used them as their dynastic languages.¹

1. The Khitan Scripts

As far as Khitan is concerned, the situation is complicated by the circumstance that it was written in two different scripts, today known as the Khitan Large Script (大文 *Dawen*) and the Khitan Small Script (小文 *Xiaowen*). Like the Tangut Script and the Jurchen Script, the two Khitan scripts have a Chinese “appearance”, meaning that they are composed of the same type of primary and secondary elements (strokes, characters), presupposing the same type of writing instruments (brush, ink), as the Chinese script. We may therefore identify all these scripts as “Sinitic” or “Sinoform” in the typological and aesthetic sense. None of them is, however, identical with the Chinese script, and only two scripts, the Khitan Large Script and the Jurchen Script, are materially “related” to the Chinese script, meaning that they may be viewed as ancient regional derivatives of the latter, a situation which also allows them to be identified as “Sinographic” writing systems, and their characters as “Sinograms”. The Khitan Small Script and the Tangut Script, on the other hand, have no material relationship with the Chinese script, which suggests that their origination may have involved a factor of conscious “invention”.²

¹ For a more comprehensive survey of the chronological context of the scripts of mediaeval peripheral China, cf. Janhunen (1994).

² The present paper will not deal in any more detail with the Tangut script. However, from the point of view of graphemic analysis, this script offers a particularly difficult challenge, since nothing is known of the principles of how it was designed. For this reason, the assumptions conventionally made about the identity of the Tangut

We know today that the Khitan Large Script and the Jurchen Script are very closely related with each other, both probably representing a continuation of a local Manchurian variety of the Chinese script. It is possible, though not verified, that this same variety, or an earlier form of it, was used already before the Liao-Jin period in other political contexts, including, perhaps, Beiwei 北魏 (386-534) and/or Balhae 渤海 (698-926). It is notable that the Khitan Large Script incorporates many Chinese characters, especially simple ones, in unchanged form, while in the Jurchen Script such characters are normally distinguished from their Chinese counterparts by using diacritics. We also know that both the Khitan and the Jurchen used this script as a mixed logo-syllabic system, with some characters functioning as logograms (with Khitan and Jurchen pronunciations) and others as syllabograms (for fixed sequences of sounds, not necessarily corresponding to phonetic syllables). In general, the number of separate characters in the Khitan Large and Jurchen Scripts is considerably smaller than in the Chinese script, and the forms of the characters are less complicated, with no functionally relevant “radical” components.

Unfortunately, the Khitan Large Script is still very imperfectly deciphered, with only a small proportion of the characters identified with meanings (logograms) and/or sounds (syllabograms). One important direction of research that has not yet been properly initiated is the systematic comparison of the Khitan Large Script characters with those of the Jurchen Script. Due to the fact that the Jurchen Script survived relatively long (till the 16th century) and was used to write a well-known language (Jurchen-Manchu), our knowledge of the Jurchen Script is rather close to “decipherment” in the sense that most of its elements have a

language are also detached from the graphic reality and cannot be considered as confirmed, as was already pointed out by Kwanten (1984, 1988).

known linguistic correlate, even if there still remain many open questions.³ On the other hand, the corpus of the Khitan Large Script is much more extensive, and in a much better state of preservation, than that of the Jurchen Script. Therefore, the Khitan Large Script is potentially a crucial source of information also for Jurchen studies. At the present stage, however, its potential cannot yet be exploited.

This leaves us only the Khitan Small Script corpus as the most important currently available direct source on the Khitan language. Since several decades, it has been known that this is a basically syllabic script, using a limited number of graphically simple syllabic signs (syllabograms), known as the Khitan Small Script “characters”. What makes the graphic image visually complicated is the convention of accumulating the syllabic signs into “blocks” corresponding to linguistic words, a convention which, incidentally, has a close analogy in the Korean Hangeul.⁴ Since a Khitan word (with derivational and inflectional suffixes) can consist of up to eight “syllables”, a block can have a graphic appearance (stroke composition) even more complex than a Chinese character—a circumstance that caused confusion during the early stages of Khitan studies, when it was not yet clear how the “Small” and “Large” scripts should be properly distinguished.⁵

The decipherment of the Khitan Small Script has involved both slow progress and rapid steps foreword starting with the early 1920s.⁶ A

³ The principal works on the Jurchen Script are Grube (1896), Kiyose (1978), Kane (1989), Jin Qicong (1984), and Pevnov (2004). Of these, only Kane comments also on the Khitan Large Script.

⁴ The difference between the two scripts is, of course, that the blocks in Hangeul are composed of phonograms. It is not known whether the Khitan Small Script can have inspired the creators of the Hangeul, for ultimately the blocks in both the Khitan Small Script and the Hangeul must have been modelled along the principle of Chinese characters.

⁵ The distinction between the two Khitan scripts was first correctly made and communicated internationally by Toyoda (1964).

⁶ Most research on the Khitan Small Script has mainly been communicated in scattered papers and a few monographs in Chinese. An important critical summary of all this work was made available for the international readership by Kane (2009).

definitive breakthrough, which for the first time yielded concrete “readings” of Khitan words, was achieved by a team active in China in the ’70s and ’80s.⁷ Since then, the most important development has been the rapid increase of the corpus, conditioned by the discovery of new texts. The currently known corpus comprises 34 published and a few unpublished epigraphic texts plus a diffuse selection of minor materials. The standard of “publication” varies, however, and not all texts have been made available in a form that can be used for textological and linguistic analysis. Even so, and in spite of the fact that the epigraphic texts tend to be stereotypic in form and content, the corpus is large enough to allow relatively detailed conclusions to be made about the Khitan language and the properties of the Small Script.

The phonetic value of the Khitan Small Script syllabic signs varies from one segment (consonant or vowel) to sequences of up to three segments. Some characters seem to be used also for longer words as what may be actual logograms. There are, of course, also undeciphered characters. Of the currently known 459 different characters, “only” 314 have been deciphered in one way or another.⁸ These include, however, a large proportion of the most frequent characters, while many of the undeciphered items are rare and may even involve mistakes. This means that even if the decipherment is not fully completed, it is already possible to render long sequences of continuous Khitan text a more or less consistent phonetic and/or semantic interpretation, with only occasional lacunae. In this situation, attention may gradually be turned away from the script to the language behind the script.

⁷ Qinggeertai & Liu Fengzhu & Chen Naixiong & Yu Baolin & and Xing Fuli (1985). For a more detailed history of Khitan Small Script studies, see Wu Yingzhe & Janhunen (2010: 20-25).

⁸ An up-to-date list of the Khitan Small Script characters is given in Wu Yingzhe & Janhunen (2010: 259-272, cf. also the discussion *ibid.* 35-48).

2. The Khitan language

The Khitan, or *Qidan* 契丹, were the dominant ethnic group in the Liaoxi 遼西 region in the period between the Beiwei and the historical Mongols. The Khitan survived as an ethnic group after the rise of the Jurchen, and written documents in the Khitan language continued to be produced almost till the end of the Jin period. It is well known from Chinese historical sources that Khitan was a distinct language, spoken by virtually all ethnic Khitan, a population whose size may have reached a million people during the height of the Liao dynasty. Khitan was not the only language spoken in the Liao state, however, for other languages, including Chinese and Jurchen, were also widely used especially in the areas conquered by the Khitan during the process of state formation. It is less clear how uniform Khitan was internally. The Khitan were composed of tribes, some of which played a more important political role in the Liao state than others, and it is quite possible that there were tribal forms of speech that deviated from the mainstream language.⁹

Apart from texts in the two Khitan scripts, there are two other types of sources on the Khitan language. These are, first, the occasional samples of Khitan, mainly lexical items, but also phrases and poems, preserved in Chinese transcription and glossing, and, second, the Khitan loanwords transmitted into neighbouring languages, especially Jurchen. As far as can be seen, these sources represent a language identical with that of the Khitan text corpus. The Chinese data are, however, often frustratingly difficult to interpret with any certainty due to the chronological, phonological, and semantic inaccuracies as well as outright errors contained in them.¹⁰ Loanword research could potentially yield much more

⁹ On the tribes, as well as on the general social history and historical demography of the Khitan, see Wittfogel & Fêng (1949).

¹⁰ Recent studies of Khitan words in Chinese sources include Sun Bojun & Nie Hongyin (2008) and Talpe (2010). The only linguistically competent work on the subject is

informative results, for it may be taken for certain that Jurchen, as a subordinate language of the Liao state, received a considerable number of Khitan loanwords.¹¹ It is also likely that the two languages were typologically similar, which means that we may occasionally use information from Jurchen to approach the structure of Khitan.

The fact that Khitan is, or was, typologically speaking, an “Altaic” language, was known already before the original sources in the language could be “read”.¹² This is now confirmed by the actual “readings” of the Khitan Small Script texts. We know, for instance, that Khitan had an elaborate system of nominal and verbal inflectional suffixes, most of which can be phonologically approximated.¹³ The syntax and morphosyntax, including the basic word order (SOV) and the various types of subordinated (converbial) and embedded (participial) sentence constructions, is also in full accordance with that attested in the other historical and modern “Altaic” languages in the region, including both Jurchen-Manchu and Mongolian. There are, however, some unexpected features, notably traces of grammatical gender (marked masculine vs. unmarked or generic feminine), a category not typical of “Altaic” typology though, incidentally, present in Middle Mongol.¹⁴

It used to be more difficult to determine what genetic group (language family) Khitan represents. “Altaic” typology as such does not indicate whether a language is Turkic, Mongolic, Tungusic, or something else. In the

Shimuněk (2007). Selected details are also discussed by Vovin (2003) and Róna-Tas (2004).

¹¹ Some pioneering work on the lexical parallels between Khitan and Jurchen has been carried out by Kane (2006).

¹² A “grammar” and collection of Khitan Small Script “texts” in digital form was compiled by a Russian team in the 1960s and ’70s, cf. Starikov & al. (1970), Arapov (1982).

¹³ So far the only systematic grammatical sketch of Khitan has been compiled by Kane (2009: 131-166), who also gives a vocabulary of 354 items (*ibid.* 83-130).

¹⁴ The role of grammatical gender in Khitan is still far from completely understood. Work on this issue has been carried out by Wu Yingzhe (2005, 2007). In spite of its importance, the issue of grammatical gender is largely unstudied in Middle Mongol, cf. Rybatzki (2003: 75).

past, when work on Khitan was solely based on the Chinese transcriptions and glosses of Khitan words, it was common to try to identify these words item by item with the different historical and extant “Altaic” languages. The result was ambiguous, since Khitan turned out to contain lexical items that could be identified variously with either Mongolic or Turkic, or also Tungusic.¹⁵ In many cases, parallel identifications were possible, leading to speculations that Khitan might be an “intermediate” idiom between, say, Turkic and Mongolic, or Mongolic and Tungusic. The problem here was that inherited elements were not properly distinguished from borrowed ones.

A more reliable method is to operate with genetically diagnostic words, such as items of basic vocabulary, which are likely to have been inherited rather than borrowed. With this method, it was initially possible to identify the language of the Tabghach, or *Tuoba* 拓跋, the leading ethnic group of the Beiwei state, as basically “Mongolic”. Since the Tabghach were the political and, quite possibly, the linguistic ancestors of the Khitan, the Mongolic identification of Khitan gained ground.¹⁶ This identification is now definitively confirmed by the information from the Khitan Small Script texts, which show beyond doubt that Khitan was a language whose basic vocabulary and grammatical resources were related to those attested in the Mongolic languages. It is important to note that this conclusion is exclusive, in the sense that Khitan *is not* an “intermediate” language and *cannot* share elements, except borrowings, with other “Altaic” languages than Mongolic.¹⁷

The term “Mongolic” needs, however, modification when used about Khitan. All other extant and historical Mongolic languages represent a single genetic node, corresponding to the language of the historical

¹⁵ Menges (1968) made an effort to identify Tungusic elements in Khitan, though we know today that most of his identifications are wrong. He had to admit himself that the material was not conclusive for the determination of the genetic position of Khitan.

¹⁶ The Mongolic identification of the Tabghach language was made by Ligeti (1971). A similar identification for Khitan is implied by Doerfer (1992, 1993).

¹⁷ Suggestions that violate this principle are occasionally encountered in the works of Khitan specialists not sufficiently familiar with comparative linguistics.

Mongols, and linguistically identifiable as Proto-Mongolic. Khitan did not descend from Proto-Mongolic but was, rather, a sister language of the latter. In other words, Proto-Mongolic and Khitan represented two branches of an even older protolanguage, a certain stage of Pre-Proto-Mongolic which could also be termed “Khitano-Mongolic”. Khitan itself may also have had sister languages belonging to the same branch, which, in that case, should be termed Khitanic. Technically, the most suitable term to describe the position of Khitan (and Khitanic) with regard to Proto-Mongolic is to identify the former as Para-Mongolic, implying that it is a question of a genetically related, but collateral, branch of the much better known Mongolic language family.¹⁸

3. The position of Khitan

The availability of direct information on Para-Mongolic in the form of Khitan Small Script texts opens up extremely important new perspectives for studies on the history of the Mongolic language family. Working with the actual Mongolic languages alone, we used to have three kinds of diachronic information: first, the comparative evidence provided by the extant Mongolic languages; second, the information contained in the historical forms of Mongolic, especially Written Mongol and Middle Mongol; and third, the potential conclusions that can be made from the comparative and historical data by the method of internal reconstruction. Only the last type of information allows us to approach the period preceding Proto-Mongolic, which itself is of a rather shallow depth corresponding to no more than 800-900 years.

¹⁸ The term Para-Mongolic was introduced by Janhunen (1995, 2003) and has since found some support in specialist literature, cf. e.g. Kane (2009: x).

The question is how far backwards the Khitan data allow us to go in the history of Mongolic. This, on the other hand, depends, on how different Khitan was as compared with Proto-Mongolic. Before the decipherment of the Khitan Small Script there was an opinion that Khitan may have been closely related to Proto-Mongolic, so closely that it was thought that Khitan could perhaps be “read” in terms of the lexical and grammatical information we have from Middle Mongol. Today we know that this is not so: Khitan is, in fact, a language rather distantly related to the Proto-Mongolic branch. To get an idea of how distant the relationship could be we may think of the neighbouring Tungusic language family, in which the southern branch, corresponding to Jurchen-Manchu (Jurchenic), is in many ways strikingly different from the northern branch, corresponding to Ewenki-Ewen (Ewenic).¹⁹

Assuming that the difference between Para-Mongolic and Proto-Mongolic was of the same chronological scope as that between the southern and northern branches of Tungusic, the breakup of the original protolanguage (Proto-Khitano-Mongolic) would have taken place at least several centuries before the emergence of Khitan as a written language. The last possible historical context for the still uniform protolanguage would seem to have been the empire of the Xianbei 鮮卑 (93-234), though the breakup may, of course, have taken place even earlier. A practical consequence of the chronological difference is that Khitan texts, which with one notable exception are not bilingual, are difficult to understand even if the script is no longer a major problem. It is not without reason that the situation has been compared with that of Etruscan: a known script but an unknown language.²⁰

¹⁹ The Tungusic family also has two transitional (or mixed) branches. For a more detailed taxonomy of Tungusic, cf. Janhunen (2011).

²⁰ The Etruscan parallel is mentioned by Kane (2009: x), who also discusses the general challenge posed by languages that can be read without being understood. On the unique bilingual Khitan text, cf. most recently Vovin (2000).

Fortunately, however, Khitan—unlike Etruscan—is not completely unknown, for it is still related to the Proto-Mongolic branch, although the relationship is so distant that it does not substantially facilitate the understanding of Khitan texts. The genetic connection is nevertheless evident from the existence of cognate words and shared morphological elements present in both Khitan and Proto-Mongolic. It is very likely that the number of cognates will continue to grow as more linguistic work is done on the Khitan Small Script texts. We should, however, not be too optimistic about the size of the comparative corpus. The total number of Khitan lexical items that can be assessed both phonetically and semantically today is still less than 500, and many of these items do not belong to the basic vocabulary; moreover, they also comprise a number of Chinese borrowings.

As it is, the number of currently known certain or plausible cognates between Khitan and Proto-Mongolic is at the range of a few dozen, that is, about ten per cent of the total known Khitan lexicon.²¹ The only way to assess the taxonomic status of Khitan with regard to Proto-Mongolic is to analyze this corpus with the methods of comparative linguistics. It is particularly illustrative to see in what respects Khitan, as compared with Proto-Mongolic, is archaic and in what respects it is innovative. Since Khitan became a written language some 200 years before Middle Mongol, one would expect that it might be in some respects more archaic. The picture is not equivocal, however, for in other respects Khitan is surprisingly “modern”, often anticipating innovations that took place in the Proto-Mongolic branch only after the breakup of the latter. This is compatible with the picture provided by the Tungusic family, in which Jurchen-Manchu may also be seen as a particularly innovative branch as

²¹ Many of the cognates have been identified over the years by Chinese scholars and are listed by Kane (2009), though his database involves mistakes and omissions.

compared with Ewenki-Ewen. Moreover, some of the innovations present in Khitan are likely to have been shared with Jurchen on an areal basis.

At this point a word of caution concerning the notation is in place. The language behind the Khitan Small Script can be approached in terms of a Romanized approximation of its phonetic structure. The Romanization is, however, not an exact reconstruction of the segmental properties of the language. This situation is due to two circumstances: on the one hand, we simply do not know the exact segmental counterparts of many Khitan Small Script characters, although we can “approximate” them; on the other, we have to consider the fact that the orthography of Khitan is not always consistent with the actual sequences of sounds. In order to show the difference between orthography and sounds, it is useful to let the Romanizations be accompanied by a more phonemically accurate “reading” (marked †), which, in turn, should be distinguished from reconstructions (marked *).²²

4. Lexical properties

As all Khitan texts of any significant length are memorial in character, containing epitaphs, eulogies, lamentations, and/or historical records, the lexicon used in them is thematically and functionally restricted. This gives the decipherer the advantage of having many parallel repetitions with minor variations, as in genealogical lists, which, in turn, allows the identification of certain crucial lexical items and phrases to be multiply verified. The obvious disadvantage is that large sections of the lexicon

²² The current system of Romanization for Khitan was introduced by Kane (2008, 2009) and developed further by Wu Yingzhe & Janhunen (2010). The phonetic reliability of the Romanized shapes varies, and not all Romanizations may be regarded as fully verified. In the present paper, the Khitan items are quoted both in the original script (linearized) and in Romanization, with a phonetic approximation given when relevant or possible.

never occur in the texts, or occur so rarely that identification is impossible. A potentially important source of lexicon is supplied by the poems which often complement epitaphic texts, but the problem here is that poetic expressions are virtually hopeless to assess without a parallel version in a known language.

In the following, a few lexical spheres relevant to comparative linguistics are examined in some more detail:

Pronouns. For genetic comparisons, personal pronouns would be an ideal source of diagnostic information. Unfortunately, first and second person pronouns do not seem to be attested in the extant Khitan corpus. A possible third person pronoun is 𐰽 *hó*, but this item has no known cognate in Proto-Mongolic. The proximal demonstrative is, however, fully comparable with Proto-Mongolic data. The Khitan shape is 𐰽 *e* ‘this’: 𐰽 *t* ‘these’, suggesting the readings †*e* : plural †*e-d*, which correspond to Proto-Mongolic **e-n=e* : plural **e-d=e*. As may be seen, the Khitan shapes look like more simple and, hence, archaic, as they lack the stem extension *-n* and the postclitic element *=e*, as attested in the Proto-Mongolic cognates.²³

On the Mongolic side, the proximal pronoun has the oblique stem **e-xü/n-* > **üün-*, which has been compared with the possibly pronominal Khitan monosyllable 𐰽 *ún* †*un*. This comparison remains unverified, but it would seem to correlate with Khitan 𐰽 𐰽 *ún.e* †*une* ‘now’, which formally corresponds to the Proto-Mongolic locative case form **e-xü/n-e* ‘upon this’, a case form also attested in **e-d/ü-x-e* ‘now’ (> Modern Mongolian *odoo*). The demonstratives are, however, not necessarily among the most stable elements of a language, which is why there is no need to expect a full correspondence between Khitan and Proto-Mongolic. It is therefore not

²³ All Khitan data are quoted from Kane (2009) and Wu Yingzhe & Janhunen (2010). On the demonstrative pronouns, cf. also Wu Yingzhe (2009, 2011).

surprising that the Khitan distal pronoun is 𐰺 *qi* ‘that’ : plural 𐰺𐰽 *qi.t*, suggesting an item totally different from Mongolic **te*.²⁴

Numerals. One of the most simple demonstrations of the relationship between Khitan and Mongolic is offered by the basic numerals. Most numeral roots in Khitan can be written in two ways: either by a single character, often for cardinals, or in terms of a sequence of characters, often for ordinals. In both cases, it is a question of syllabic signs with a phonetic value, though some of the single characters for numerals still lack a phonetic approximation. From the combined information of the two types of spelling we can establish the following basic numeral stems: 2 𐰺𐰽 *ci.ur-* †*jur-*, 3 𐰺𐰽𐰽 *hu.ur-* †*hur-*, 4 𐰺𐰽𐰽𐰽 *t.ur-* †*dur-*, 5 𐰺𐰽𐰽𐰽𐰽 *tau* †*tau*, 7 𐰺𐰽𐰽𐰽𐰽𐰽 *da₂.lo-* †*dal-*. The similarity to Mongolic 2 **jir-* (or **jir-*),²⁵ 3 **gur-*, 4 **dör-*, 5 **tab-*, 7 **dal-* is unmistakable, and it would be impossible to explain the situation by assuming borrowing. The higher numerals for the powers of ten 100 𐰺𐰽𐰽𐰽𐰽 *jau*, 1000 𐰺𐰽𐰽𐰽𐰽𐰽 *ming*, 10 000 𐰺𐰽𐰽𐰽𐰽𐰽𐰽 *tum* also have Mongolic cognates: **jaxu-*, **mingga-*, and **tüme-*, though they are less diagnostic, since they would have been more liable to be borrowed.

We also know the approximate phonetic shape of the Khitan numeral stem 9 𐰺𐰽𐰽𐰽𐰽 *is* †*is-*. This item is often compared with the Modern Mongolian numeral 9 *is* ~ *ys*. This comparison is wrong, however, for the Mongolian item derives from **yer-sü/n* (as also in 90 **yer-e/n*), an innovation of the

²⁴ In this case, the discrepancy has also been explained by drawing the Romanization of the Khitan character into question. Most recently, Wu Yingzhe (2011: 00-00) has suggested the Romanization *te*, congruent with Mongolic **te*, though *mun*, which would correspond to Mongolic **mön* ‘this’, has also been proposed. Unfortunately, such reinterpretations are not compatible with the evidence supporting the Romanization *qi*, as established on the basis of another (ethnonymic) attestation by Kane (2009: 73), cf. also Wu Yingzhe & Janhunen (2010: 65-66).

²⁵ Since the Proto-Mongolic reconstructions are, in principle, well known, the present paper will not discuss them in the detail. It may nevertheless be noted that the numeral root for 2 is harmonically ambiguous: palatal vocalism is suggested by **jitiixer* ‘second (wife)’ and possibly **jirin* ‘two (females)’, while velar vocalism is suggested by **jira/n* ‘sixty’ (2x3x10).

Proto-Mongolic lineage, as is also confirmed by data from the “teens” in Jurchen-Manchu.²⁶ Another innovation in Mongolic is the numeral 6 **jir-gu-xa/n* (2x3), which must have replaced the original numeral likely to hide behind the Khitan character 𐰇 SIX. Judging by the corresponding “teen” in Jurchen-Manchu, the Khitan item may have been †*nil-*, but this shape cannot yet be confirmed by the Khitan Small Script.

It may be noted further that the Khitan basic numerals seem to lack the stem extension **-pA/n > *-bA/n ~ *-xA/n*, as present in the Mongolic items for the first decade 3 **gur-ba/n*, 4 **dör-be/n*, 7 **dal.u-xa/n*, and others. This element might, then, represent an innovation specific to the Proto-Mongolic lineage, though it is also possible that the Khitan numeral system was secondarily simplified; in fact, we do not know what the exact shapes of the Khitan numerals were in absolute cardinal use. On the other hand, the Khitan numerals 2 †*jur-*, 3 †*hur-*, 4 †*dur-* contain the segment **r*, which most probably is a derivative element. This element is also present in Mongolic, meaning that it must represent an innovation common to both the Proto-Mongolic and the Para-Mongolic lineage.²⁷

Terms for the four seasons. Among the surprises offered by the comparative material are the terms for the four seasons, which are virtually identical in Khitan (†) and Proto-Mongolic (*): 𐰇𐰏 *heu.úr* †*haur* = **kabur* ‘spring’, 𐰇𐰏𐰓 *ju₃.un* †*jun* = **jun* ‘summer’, 𐰇𐰏𐰓𐰓 *n.am.úr* †*namur* = **namur* ‘autumn’,

²⁶ On the teens in Jurchen-Manchu, cf. Janhunen (1993). Although these items were certainly borrowed from a Mongolic language, we do not know whether the borrowing happened before or after the split of the Proto-Mongolic and Para-Mongolic lineages. The structure of the teens in Jurchen-Manchu differs from that attested in the language of the Khitan texts.

²⁷ Using the method of internal reconstruction, the **r* in 3 **gur-* may be compared with the **t* present in Mongolic 30 **guc-i/n < *gut-i/n*, though the background of this correspondence is unknown. The case of 4 **dör-* : 40 **döcin* may be more complicated since this basic digit is also attested in some Mongolic languages (Shirongolic) as **der-*, while the corresponding decade is present, as a loanword, in Tungusic in the unexpected shape (**)deki(n)*, cf. Doerfer (1985: 78-79).

𐰺𐰽 *u.ul* †*uul* = **öbül* ‘winter’. Since the possibility of a wholesale borrowing is extremely unlikely, it must be a question of cognates. Moreover, the Khitan items, when not fully identical with their Proto-Mongolic counterparts, show a somewhat greater degree of phonological innovation. This would seem to confirm that Khitan was generally more innovative, or also more “worn”, than Proto-Mongolic.

The terms for the four seasons also provide an important clue to understanding the innovations shared by Proto-Mongolic and Para-Mongolic. The medial nasal **m* in **namur* ‘autumn’ must represent the same segment as the medial obstruent **b* in **kabur* ‘spring’. In other words, it is a question of a suffix, possibly reconstructable as Pre-Proto-Mongolic **-pUr*, which is represented as **-mUr* after a syllable with an nasal onset, and as **-bUr* elsewhere. Possibly, the element **(-)büil* in **öbül* ‘winter’ is also relevant in this context. In any case, the change **p* > **m*, which may be seen as a case of progressive distant assimilation, is likely to have taken place in the common protolanguage of Proto-Mongolic and Para-Mongolic.²⁸

Kinship terms. In view of the numerals and the terms for the four seasons it is curious that there is no overall correspondence in the realm of kinship terminology. Several Khitan kinship terms, including 𐰺 *ai* ‘father’, 𐰽 *ia* ‘elder brother’, and 𐰺 *au* ‘elder sister’, have no obvious cognates on the Mongolic side. In other cases the correspondences are uncertain: 𐰺 *mo* ‘woman, mother, wife’ (plural 𐰺𐰽 *mo.t*) and 𐰺 *bu* ‘grandfather’ (in 𐰺 𐰺 *bu ai* id.) have been compared with Mongolic **eme* ‘woman’ resp. **ebü-gen*

²⁸ The reconstruction of the original consonant behind the variation **b* ~ **m* is not a trivial task, of course, and it is possible that **b* would be a better choice than **p*. In other items, the variation also involves **x*, as in the numerals, in which **m* is present in Mongolic 8 **nai-ma/n*. For the time being we do not know what the phonetic shape of the corresponding Khitan numeral was.

‘old man’, but the issue cannot be considered as fully concluded.²⁹ The comparison between 𐰇𐰏 *b.qo* ‘child’ (plural 𐰇𐰏𐰢𐰏 *b.hu.án*) and Mongolic **baga* ‘small’ > ‘child’ is also problematic.

There are, however, also good and non-trivial correspondences. These include 𐰇𐰢 *na.ha* †*naha* (plural 𐰇𐰢𐰏𐰢 *na.ha.án.er*) ‘maternal uncle’ = **naga-cu* id., 𐰇𐰏𐰢 *k.iú* ~ 𐰇𐰏𐰢 *x.iú* †*keu* ‘younger sister’ = **keü* ‘child’, and very probably 𐰇𐰏 *deu* †*deu* (genitive 𐰇𐰏𐰢 *deu.un*) ‘younger brother’ = **de(x)ü* id.³⁰ In two items, Khitan would seem to have a monosyllabic root (CV) where Mongolic has a bisyllable, apparently a derivative: 𐰇 *ku* †*ku* ‘person’ (genitive 𐰇𐰏𐰢 *ku.ú.un*) = **kü-xiün* id.,³¹ 𐰇𐰏 *n.o* †*no* ‘spouse’ = **nö-kür* id., ‘friend’. In the item 𐰇𐰏𐰢 *n.ai.ci* †*naiji* ‘friend’ = **nai-ji* id. both branches have a derivative; the root **nai* ‘friendship’ is preserved in Mongolic, and it is also attested in other derivatives like **nai-r* ‘concord, festivity’.

Root structure. Khitan seems to have been characterized by the same type of basic phonotactic restrictions as the other “Altaic” languages, including both Jurchen and Proto-Mongolic. This means, among other things, that there were no syllable-initial or syllable-final consonant clusters. Most lexical items are bisyllabic ((C)V(C)CV(C)), but there are also conspicuously many monosyllables. Among the latter, those ending in a consonant ((C)VC) can have direct cognates in Mongolic, as in the case of

²⁹ Wu Yingzhe (2009) argues, certainly correctly, that in some cases a Khitan character can imply a “hidden” initial vowel. If the Khitan phonemic shapes were something like †*eme* resp. †*ebu* the cognateship with Mongolic would be in no doubt.

³⁰ The only problem in the item for ‘younger brother’ is that the Romanization of the character is not verified by independent information. The genitive form confirms, however, that the underlying syllable ended in †*u*, suggesting that the Romanization is correct.

³¹ Mongolic **küxiün* has the variant **kümiün* (as in Written Mongol and Oirat), suggesting that the original shape was **kü-piün* (with early dialectal nasalization of the medial consonant).

𐰇𐰏 *go.er* ‘tent’ > ‘household’ = **ger*.³² Khitan has, however, also many monosyllabic vowel stems ((C)V), a type absent in Proto-Mongolic (except in pronouns). In the comparative context it seems that the monosyllabic vowel stems in Khitan are an archaic trait eliminated on the Mongolic side by way of secondary suffixation, as in the above-mentioned items †*ku* ‘person’, †*no* ‘spouse’.

Importantly, the method of internal reconstruction allows monosyllabic vowel stems to be established also for a very early stage of the Mongolic lineage, as in the collective nouns formed by *-*d* (for countables) and *-*s* (for liquifiables). Only one of these is so far identified in the Khitan Small Script database: 𐰇𐰏𐰏 *ci.i.is* †*cis* ‘blood’ > ‘blood relative’ = **ci-s-ü/n* ‘blood’, presupposing the monosyllabic root **ci*. As may be seen, this item shows the collective suffix *-*s* also in Khitan, suggesting that this group of nouns was formed already in the common protolanguage of the Proto-Mongolic and Para-Mongolic lineages.³³

5. Diachronic phonology

No systematic picture of Khitan phonology is yet possible to draw. We cannot, for instance, reconstruct the exact configuration of the systems of vowels and consonants. This is due to the nature of the script, which involves multiple cases of both under- and over-differentiation, as well as a considerable amount of orthographical variation. We also have to reckon

³² The exact “reading” of the Khitan word is difficult to reconstruct. The comparative evidence would suggest the shape †*ger*, but the orthographical image is exceptional and might imply something more complex, especially as far as the vowel quality is concerned.

³³ On the Pre-Proto-Mongolic collectives in *-*d* resp. *-*s*, cf. Janhunen (1996: 210-215). On the Mongolic side, these nouns are always expanded by the element *-*U/n*. It may be noted that the item for ‘blood’ is also the base for the Khitan term for ‘filial piety’, see Kane (2004), Shimunek (2007: 71).

with the possibility that Khitan changed in the course of time: the currently available corpus of Khitan Small Script texts covers a period of over a hundred years (1053-1175), while some of the orthographical conventions are likely to date from the time when the script was created (924-925). In general, work on the Khitan phonological system is closely connected with the reconstruction of Liao Chinese, a little known form of speech, transitional between local Late Middle Chinese and Early Mandarin.³⁴ On the other hand, Khitan phonology is likely to share many features with Jurchen on an areal basis.

In the following some general points of relevance in the diachronic context are discussed in comparison with the Proto-Mongolic lineage:

Vowel Rotation. As a working hypothesis it is reasonable to assume that Khitan originally had a vowel system similar to Pre-Proto-Mongolic. This system would have comprised 8 vowels, divided into 4 back (*a *o *u *i) and 4 front (*e *ö *ü *i), as well as 4 lower (*a *e *o *ö) and 4 higher (*i *i *u *ü) vowels. A similar system, with minor modifications, may be reconstructed for Proto-Turkic, Proto-Tungusic, and even Proto-Koreanic. All over the region, the system has, however, undergone a process of vowel rotation, in which the original front vowels have been raised and velarized, while the original back vowels have been lowered and, in some languages, pharyngealized. A typical example of the effect of vowel rotation is the development of the pair *u - *ü = phonetically [u - y] to o - u = [o - u], as observed in languages such as Manchu, Dagur, and Korean.³⁵

Vowel rotation in Northeast Asia is a relatively recent phenomenon, not yet observable with certainty in Proto-Mongolic. It is, therefore, important to note that it seems to have been present in Khitan. Although

³⁴ On Liao Chinese, cf. Kane (2009: 227-264). Tentative outlines on Khitan phonology are given by Shimunek (2007: 38-52) and Takeuchi (2007).

³⁵ For a general discussion of the areal and typological background of vowel rotation in the languages of Northeast Asia, cf. Janhunen (1981).

the vowel letters contained in the Romanizations should not be taken at face value, there are examples suggesting the developments $*\ddot{u} > \uparrow u$ and $*u > \uparrow o$, as in 𐰽 *uni* $\uparrow uni$ ‘ox’ = $*\ddot{u}ni-xe/n$ ‘cow’, 𐰽 *on-* $\uparrow on-$ ‘to ride’ = $*unu-$ id. The ultimate impact of vowel rotation is the reduction of the paradigm towards a simple five-vowel system (*a e i o u*).³⁶ We do not know whether Khitan had reached this stage, but there are indications of, at least, a neutralization between $*\ddot{o}$ and $*\ddot{u}$, cf. 𐰽 *s.uni* ‘night’ = $*s\ddot{o}ni$ id. On the other hand, there is also evidence of a more general neutralization of rounded vowels, cf. e.g. the numerals 3 𐰽 *hu.ur-* $\uparrow hur-$ = $*gur-$ vs, 4 𐰽 *t.ur-* $\uparrow dur-$ = $*d\ddot{o}r-$.³⁷

*Preservation of *p.* Another widespread areal feature in Northeast Asia concerns the original strong (voiceless/aspirated) labial stop ($*p$), which has been variously spirantized ($> f$), velarized ($> x$), pharyngealized ($> h$), or lost ($> \emptyset$) in almost all languages and language families of the region, including Turkic, Mongolic, Tungusic, and even Japonic.³⁸ While vowel rotation seems to have proceeded from east to west, the spirantization of the strong labial stop moved in the opposite direction, being most ancient in the west (Turkic) and most recent in the east (Tungusic and Japonic). There is only one language family of the “Altaic” sphere, Koreanic, in which this phenomenon is totally absent.³⁹

³⁶ The system can be secondarily increased by the introduction of a new set of palatal vowels, as has happened in Korean, as well as in several varieties of Mongolic.

³⁷ In numerals we have, of course, to consider also the possibility of analogical levelling between neighbouring items.

³⁸ The phenomenon is also attested in a few Uralic languages. Starting with Pelliot (1925), particular attention in comparative Altaic studies has been paid to the *h*-stage, though the implications of the issue have not always been correctly understood.

³⁹ Another language family in which the phenomenon is not attested is Amuric, today represented by the single language (isolate) of Ghilyak (Nivkh), but earlier distributed more widely in Manchuria, including, quite possibly, the northern neighbourhood of Korean.

Importantly, the strong labial stop is also preserved in Khitan. The same seems to have been the situation in early Jurchen, while spirantization ($> f$) took place in later Jurchen, as attested in Manchu. The status of Khitan in this respect was known already from the lexical data preserved in Chinese rendering, as in 頗 $\dagger po = *po$ ‘time’ = Pre-Proto-Mongolic $*pon$ (= Jurchen $\dagger po$) $>$ Proto-Mongolic $*xon$ $>$ Modern Mongolian on ‘year’.⁴⁰ Today, we have a few more examples, including 𐰽 $p.ar$ $\dagger par(a)$ ‘people’ = $*para$ $>$ $*xara/n$: (plural) $*xara-d$ $>$ $ar(a)d$ id., 𐰽𐰺𐰸 $p.ul.uh$ $\dagger pulu(-h)$ ‘intercalary month’ $<$ ‘more’ = $*püle-xü$ ‘more, extra’, as well as 𐰽𐰺𐰽 $p.úr.s$ $\dagger pur(e)s$ ‘descendants’ = (plural) $*püre-s$ ‘seeds’.

*Spirantization of *k.* Very much like the strong labial stop $*p$, the corresponding velar stop $*k$ has also tended to undergo spirantization ($> h$) and pharyngealization ($> h$), more rarely loss ($> \emptyset$), in the languages of Northeast Asia. This tendency is typically older and/or more prominent in those languages that preserve, or have until recently preserved, $*p$ intact. Therefore, we find the development $*k > h$ as a relatively early phenomenon in languages like Korean and Jurchen-Manchu,⁴¹ while in the Proto-Mongolic lineage (as well as in Turkic) it is much later. Depending on the language, the development may have contextual restrictions; it is particularly common that it is present only before original back vowels.

In Khitan, we have, in fact, examples of preserved $*k$ before original front vowels, as in 𐰽 ku $\dagger ku$ ‘person’ (genitive 𐰽𐰺𐰽 $ku.û.un$) = $*kü-xün$

⁴⁰ On this item, cf. Kane (2009: 68, 122-123). The Jurchen word is, of course, a borrowing from some early Mongolic form of speech. It may be noted that the Khitan “reading” is $\dagger po$, while Mongolic and Jurchen suggest the presence of a final nasal, i.e. $*pon$. There are also other cases in which Khitan and the Proto-Mongolic lineage differ in the use of the final nasal $*n$ in nominals. The reasons underlying these differences are not known.

⁴¹ The spirantization of $*k$ in Jurchen-Manchu has been the object of some dispute. However, the development seems to have been regular in initial position, as maintained by Näher (1999); for a different explanation, cf. Vovin (1997).

id. The variation in 𐰇𐰏 *k.iú* ~ 𐰇𐰏 *x.iú* †*keu* ‘younger sister’ = **keü* ‘child’ might suggest that there was a tendency to spirantize **k* also in this position, another possible example being 𐰇𐰏𐰣 *x.ui.ri* ‘to arrive’, which may or may not correspond to Proto-Mongolic **kiir-* id.⁴² Before original back vowels, spirantization is confirmed by 𐰇𐰏 *heu.úr* †*haur* = **kabur* ‘spring’. Again, caution should be exercised with regard to the letters used in the Romanization (<*k x h*>), the exact phonetic values and phonemic relationships of which are not known. It may be noted that, at least at the level of Romanization, a spirantized velar in Khitan can also correspond to the Mongolic weak velar stop **g*, as in 3 𐰇𐰏 *hu.ur-* †*hur-* = **gur-*.

Vowel contraction. The Proto-Mongolic lineage had a medial velo-laryngeal spirant **x* [h], which is represented as a segment in Written Mongol, but which has been lost in all extant Mongolic languages, and even in Middle Mongol, with vowel contraction (long vowels and diphthongs) as a result. The segment itself was of a heterogeneous origin and may in some cases even have been “original”.⁴³ The issue is complicated by the possibility that there may also have existed “original” diphthongs (like **ai* **au*), though the comparative material does not allow them to be distinguished reliably from sequences with a medial **x* (like **axi* **axu*).

Proto-Mongolic **x* is, in any case, normally represented as zero in what may probably be understood as diphthongs in Khitan, as in 100 𐰇𐰏 *jau* †*jau* = **jaxu/n*. However, the segmental counterpart of Proto-Mongolic **b* also seems to be lost in Khitan when followed by a rounded vowel, as in 5 𐰇𐰏 *tau* †*tau* = **tabu/n*, 𐰇𐰏 *heu.úr* †*haur* = **kabur* ‘spring’. The fact that there is no medial consonant in these cases is confirmed by the use of the characters 𐰇𐰏 *jau* and

⁴² This correspondence would be valid if the Khitan item is to be read †*hur-*, but the peculiar orthographical image may actually point to a different shape. In any case, there must have been a difference with regard to the numeral 3 †*hur-*.

⁴³ On **x* in Mongolic, cf. Janhunen (1999). In earlier research, this segment was often confused with **g*, with which it is graphically indistinguishable in Written Mongol.

𐰇 *tau* for the Chinese term 𐰇 𐰇 *jau.tau* †*jautau* ‘punitive commissioner’ = 招討 **jawtaw* (*zhaotao*). The use of the character 𐰇 *tau* in the word 𐰇 𐰇 𐰇 *tau.li.a* ‘hare’ = **taula-i* id. is also significant, though the phonological background of this “rebus” remains unclear.⁴⁴

The fate of **x* in monophthongoid contexts in Khitan is less clear, which is why comparisons like 𐰇 *ún* †*un* = **e-xii/n-* are uncertain. A possible example would be offered by 𐰇 *qa* ‘emperor’, but this item is ambiguous, since it could correspond to either **ka.n* ‘prince’ or **kaxa.n* ‘emperor’ on the Mongolic side. The genitive 𐰇 𐰇 𐰇 *qa.ha.án* ‘of the emperor’ is also enigmatic since it seems to contain a medial **g*, as in 𐰇 𐰇 *na.ha* †*naha* ‘maternal uncle’ = **naga-cu* id. It is possible that the actual Khitan readings should be †*kaga* : †*kaga-n*, in which case the Khitan word would correspond to Turkic **kaga.n*, rather than to Mongolic **kaxa.n*. Altogether, this is a word that seems to involve an unknown network of borrowings.

Vowel elision. The loss of vowels in non-initial syllables is a trivial process observed in many languages. The phenomenon may concern all short (single) vowels, or only those in certain positions, or those with certain qualities. In Northeast Asia, an early vowel elision may be established for several language families, including Turkic and Koreanic, while other families, including Mongolic and Tungusic, show a less systematic, or at least chronologically later, tendency to lose vowels.⁴⁵ A special feature of

⁴⁴ The issue depends on what part of the Proto-Mongolic numeral Khitan †*tau* corresponds to: only to the root **tab*, or to the entire bisyllabic sequence **tabu*. The word **taulai*, on the other hand, is one of the items containing an “original” diphthong with no medial consonant in Written Mongol, a situation further complicated by the fact that the Turkic counterpart **tabish-gan* has a medial **b*. However this may be, the connection between ‘five’ and ‘hare’ was among the strongest pieces of evidence in favour of the Mongolic identification of Khitan during the early phases of the decipherment of the Khitan Small Script, cf. e.g. Kara (1975: 165-166).

⁴⁵ The diachronic fact of vowel elision in a language can be easily established and demonstrated by external comparisons with other languages with preserved vowels. In Turkic and Korean, for instance, the phenomenon is confirmed by comparisons

Jurchen-Manchu (and certain forms of Mongolic) is the loss of vowels in open second syllables (the so-called “Mittelsilbenschwund”).

In Khitan, the nature of the script makes it often difficult to verify the presence or absence of vowels in all positions, including even word-initially. Many Khitan characters, irrespective of what Romanizational shape is used for them, refer basically to a consonantal core, which may be preceded (VC) and/or followed (CV) by a vowel. Items such as 𐰽𐰺 *b.as* ‘again, also’ = **basa* id. and 𐰽𐰾 *p.ar* ‘people’ = **para-* id. may, therefore, well have contained a final vowel in Khitan. On the other hand, the presence of a vowel letter in the Romanization does not necessarily mean that there was a segmental vowel in the Khitan word. We cannot, therefore, be certain that items such as, for instance, 𐰽𐰺 *i.ri* ‘name’ = **nere* id. (with a secondary initial nasal) and 𐰽𐰾 *m.ri* ‘horse’ = **mori/n* id. ended in a vowel.

Even so, the circumstance that final vowels are retained in Jurchen-Manchu suggests that Khitan most probably also retained them. This is, incidentally, also suggested by the fact that certain suffixes ending in a vowel (-CV) have positionally alternating variants, although it is not necessarily a question of regular vowel harmony.⁴⁶ It is also important to note that the counterparts of Mongolic long vowel elements (diphthongs and contracted vowels) are in Khitan rendered by using additional vowel letters, as in 𐰽𐰺𐰾 *t.qo.a* ‘chicken’ = **taki-xa* id., 𐰽𐰾𐰺 *mu.ho.o* ‘snake’ = **moga-i* id., and also 𐰽𐰾𐰺 *tau.li.a* ‘hare’ = **taula-i* id. For the time being we cannot reconstruct the Khitan shapes of such items with any certainty, but the orthography suggests that they may have involved complex vowel elements (diphthongs or long vowels) also in Khitan.

such as Turkic **er* ‘man’ = Mongolic **ere*, Korean *kom* ‘bear’ = Japanese *kuma*. Another language that has lost vowels is Ghilyak, as may be seen from examples such as Ghilyak *camng* ‘shaman’ = Manchu *saman*. Note that all these examples involve areal contacts (loanwords), rather than cases of genetic relationship.

⁴⁶ An example is offered by the dative case ending, Romanized as *-de* ~ *-do* ~ *-du*, cf. Kane (2009: 136-138). The nature of “vowel harmony” in Khitan is still an open issue.

*

It has to be stressed that only a small selection of diagnostic lexical and phonological properties of Khitan has been discussed above. Much more remains to be said, and even more remains to be discovered. What is, however, certain is that the material is consistent with the status of Khitan as a Para-Mongolic language. The distance between Khitan and Proto-Mongolic is clearly large enough to have made immediate communication between the two speech communities impossible. At the same, the similarities are conspicuous enough to have been evident even for the naïve speaker. The real situation may have been modified by the presence of intermediate idioms of which we have no direct information.

As far as the position of Khitan on the archaic—innovative scale is concerned, the situation is ambiguous. Even so, at least phonologically, Khitan may be characterized as an innovative language, which in most respects had evolved more rapidly than the lineage leading to Proto-Mongolic. Many areal innovations reached Khitan earlier than the Proto-Mongolic lineage. The reasons for the different speed of evolution must be searched in the geographical, demographical and political situation. In the centuries preceding the Liao period, Khitan had become the language of a rapidly growing and highly mobile population which, moreover, contacted on a wide scale with a variety of other speech communities. For the Proto-Mongolic lineage, such a period of intensive growth and contacts was yet to come.

Abstract:

Khitan was the dynastic language of the Liao empire in Manchuria and Northern China (907-1115). Although today extinct, samples of Khitan are preserved in two native scripts, known as the Khitan Large Script and the Khitan Small Script. Both scripts may be classified as “Sinitic” or “Sinoform” in the typological sense, though only the Large Script has a direct connection with the Chinese script. Recent progress in the decipherment of, in particular, the Khitan Small Script allows the lexicon and grammar of the Khitan language to be assessed in much more detail than before. Khitan may be defined as a Para-Mongolic language, meaning that it represents a branch related to, but collateral with, the extant and historically known Mongolic languages. The present paper examines the genetic position of the Khitan language with regard to Mongolic with the help of the methods of comparative linguistics, as applied to the deciphered Khitan language material.

Keywords: Sinitic scripts, Khitan Small Script, Khitan language, Para-Mongolic, reconstruction, decipherment

Discussion: Khitan: Understanding the language behind the scripts

Dankook University, KOREA

1. General Review

Professor Janhunen of the University of Helsinki is both a well-known Altaicist and also a leading scholar in the research of Manchu and Mongolian. The paper presented at this conference relates to his previous research on the tribes and peoples of the Manchu region. In particular Janhunen recently attempts extensive analysis of not only the languages themselves but also their relationship with history, culture and folk customs.

By attempting the phonological analysis of Khitan, his work can be seen as very original. One reason for this being that the number of scholars referencing the phonology of Khitan in detail is very small. Also, another characteristic of the work is that Prof. Janhunen has described Khitan as being located beside Mongolian and not as its direct ancestor as many scholars have before. More specifically he would like to place Khitan on a separate branch of Altaic having equal standing with Turkic and Mongolic.

On the other hand, the Khitan small script has not yet been completely deciphered and many difficulties persist in the research. The need to

supplement the research to overcome these difficulties with pieces of literature and annotations written in Chinese is a splendid opinion.

2. Discussion

The presenter would like to locate Khitan not as a direct ancestor of Mongolian but rather as a distinct language. However many of the vocabulary items cannot be freed from the Mongolic category. Is this an inability to establish certainly the characteristics differentiating Khitan from Mongolic?

In the research of Sun Bojun 孫伯君 and NIE Hong-yin 聶鴻音 (2008) the authors restored some 300 Khitan words written with Chinese characters through the phonology of Middle Old Chinese and compared them with Altaic languages. In this research considerable reconstruction of Khitan's vowels and consonants has been made. Do you have any intention to use this research in the future?

If one compares Khitan written in Chinese with Korean, the majority of vocabulary as seen below can be linked to Korean (Yi Seongkyu 2010, 2011). Will you do research comparing Korean to Khitan in the future?

(阿斯 / *as / 아사(달), 孤穩 / *güyön / 곱, 捏咿呪 / *neri / 날, 女古 / *nürgü / 누른, 于越 / *üyö / 우거, 樺 / *qa / 활, 討 / *taw / 다섯, 陶里 / *toil / 토끼, 爪 / *jo / 온, 阿主 / *ajü / 아주(머니), 暴里 / *böri / 부리, 墮瑰 / *dögü / 문(가야어), 剋 / *ga / 벼슬 이름(帥). 彌里 / *miri / 모라(牟羅).

If we look at the recent trend in Khitan research, very detailed analyses of the pronunciation of the Chinese characters used to write Khitan are taking place (Wu Yingzhe 吳英喆, Jiruhe 吉如何), but judging from this why is no detailed phonological research about Khitan vocabulary being done?

It is known that Prof. Janhunen has a wide understanding of Manchu-Tungus. To what degree are Khitan and the Manchu-tungusic languages related?
